

Experiment No. : 09

Aim: To implement Booth's algorithm.

Theory:

BOOTH'S Algorithm in C -

A *multiplication algorithm* called *Booth's algorithm* is used to multiply two signed *binary values*.

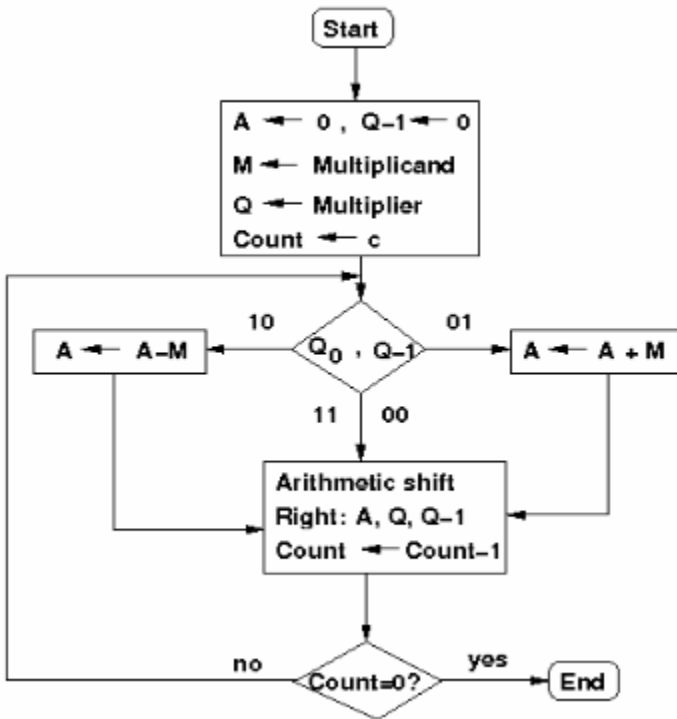

The technique increases processing efficiency by reducing the amount of addition operations needed for multiplication. It accomplishes this by performing a number of *shifts* and *adds*, which are easily accomplished by straightforward hardware circuits.

Booth's Multipliers:

Booth's multiplication algorithm is an algorithm which multiplies 2 signed integers in 2's complement. The algorithm is depicted in the following figure with a brief description. This approach uses fewer additions and subtractions than more straightforward algorithms

- The multiplicand and multiplier are placed in the m and Q registers respectively.
- A 1 bit register is placed logically to the right of the LSB (least significant bit) Q₀ of Q register. This is denoted by Q₋₁. A and Q₋₁ are initially set to 0.
- Control logic checks the two bits Q₀ and Q₋₁. If the two bits are same (00 or 11) then all of the bits of A, Q, Q₋₁ are shifted 1 bit to the right.
- If they are not the same and if the combination is 10 then the multiplicand is subtracted from A and if the combination is 01 then the multiplicand is added with A.
- In both the cases results are stored in A, and after the addition or subtraction operation, A, Q, Q₋₁ are right shifted. The shifting is the arithmetic right shift operation where the left most bit namely, A_{n-1} is not only shifted into A_{n-2} but also remains in A_{n-1}.
- This is to preserve the sign of the number in A and Q. The result of the multiplication will appear in the A and Q

Flowchart:

Booth's Algorithm Design Steps:

1. Start
2. Get the multiplicand (M) and Multiplier (Q) from the user
3. Initialize $A = Q_{-1} = 0$
4. Convert M and Q into binary
5. Compare Q_0 and Q_{-1} and perform the respective operation.

$Q_0 Q_{-1}$	Operation
00/11	Arithmetic right shift
01	$A + M$ and Arithmetic right shift
10	$A - M$ and Arithmetic right shift

6. Repeat steps 5 till all bits are compared
7. Convert the result to decimal form and display
8. End

Constraints of this program:

- The number entered must be in between the range $-16 < \text{Number} \leq 16$
- For number greater than 16 this algorithm fails.
- Range is calculated by the formula 2^k . So for 5 bit number it will be 32 bits, then by splitting the range we can say -16 to +16 and when 0 is considered we say it as -15 to +16
- Same steps are followed for 4 bit numbers
- -15 to 16 for 5 bits
- -7 to 8 for 4 bits

Output of few test cases:

Consider input of 12 and -2 the product is -24 so the binary format of the number would be 1111101000 which is the required result.

Conclusion: Booth's Multiplication algorithm has been successfully implemented in C.
